NLP Assignment 1

In this assignment, you are asked to write a program to utilize the training data to generate your *n*-gram language model with Good-Turning Smoothing, and to use your *n*-gram language model to calculate the probability of a sentence.

Given a sentence $s = w_0...w_{n-1}$ with length n, we can use the training data to calculate the count of w_i (unigram) and $w_i w_{i+1}$ (bigram). And we can also calculate $P(w_i)$ and $P(w_{i+1} \mid w_i)$, which are defined as:

$$P(w_i) = \frac{Count(w_i)}{\sum_{i} Count(w_j)}$$

$$P(w_{i}, w_{i+1}) = \frac{Count(w_{i}, w_{i+1})}{\sum_{i} Count(w_{j}, w_{j+1})}$$

$$P(w_{i+1} \mid w_i) = \frac{P(w_i, w_{i+1})}{P(w_i)}$$

where $Count(w_i)$ and $Count(w_i, w_{i+1})$ is the count of w_i and $w_i w_{i+1}$ in the training data.

The probability of *s* is defined as:

$$P(s) = P(w_0) \times P(w_1 \mid w_0) \times P(w_2 \mid w_1) \times ... \times P(w_{n-1} \mid w_{n-2})$$

To avoid the probabilities of unseen unigrams or bigrams being zero, we use Good-Turning Smoothing to calculate the smooth count of w_i and (w_i, w_{i+1}) , $Count*(w_i)$ and $Count*(w_i, w_{i+1})$.

$$Count*(w_i) = (Count(w_i) + 1) \times \frac{N_{Count(w_i)+1}}{N_{Count(w_i)}}, \text{ if } Count(w_i) < k$$

$$Count*(w_i) = Count(w_i), \text{ if } Count(w_i) \ge k$$

$$Count * (w_i, w_{i+1}) = (Count(w_i, w_{i+1}) + 1) \times \frac{N_{Count(w_i, w_{i+1}) + 1}}{N_{Count(w_i, w_{i+1})}}, \text{ if } Count(w_i, w_{i+1}) < k$$

$$Count * (w_i, w_{i+1}) = Count(w_i, w_{i+1}), \text{ if } Count(w_i, w_{i+1}) \ge k$$

where N_c is the frequency of frequency c, which means the number of words appearing c times.

Also, the $P(w_i)$ and $P(w_{i+1}, w_i)$ can be redefined as:

$$P(w_i) = \frac{N_1^u}{N_0^u N_1^u}, \quad N_0^u = V - N_1^u - N_2^u - N_3^u, \text{ if } Count(w_i) = 0$$

$$\begin{split} P(w_i) &= \frac{Count *(w_i)}{N^u}, \text{ if } \quad 0 < Count(w_i) < k \\ P(w_i) &= \frac{Count(w_i)}{N^u}, \text{ if } \quad Count(w_i) \ge k \\ P(w_i, w_{i+1}) &= \frac{N_1^b}{N_0^b N^b}, \quad N_0^b = V^2 - N_1^b - N_2^b - N_3^b ..., \text{ if } \quad Count(w_i, w_{i+1}) = 0 \\ P(w_i, w_{i+1}) &= \frac{Count *(w_i, w_{i+1})}{N^b}, \text{ if } \quad 0 < Count(w_i, w_{i+1}) < k \\ P(w_i, w_{i+1}) &= \frac{Count(w_i, w_{i+1})}{N^b}, \text{ if } \quad Count(w_i, w_{i+1}) \ge k \end{split}$$

where k is a constant (in this assignment, we set k=10), N^u is the count of unigram in training data, N^b is the count of bigram in training data, N^u_c is the is the frequency of frequency c in unigram, N^b_c is the is the frequency of frequency c in bigram, c, which means the number of words appearing c times, and V is the vocabulary size (we set V=80000).

The sample output is shown below.

Note: All punctuations are treated as words, so you should not remove them. Sentences are separated by newline, and sentences must be lowercase. Finally, you need to provide a compressed file containing source codes, executable file, and introduction document which has to include the program environment. For your exe file, TA should be able to input some test string to evaluate your program.
